

TRANSACTIONS OF SOCIETY OF ACTUARIES 1991-92 REPORTS

III. 1982-1988 INDIVIDUAL ORDINARY MORTALITY TABLE*

This mortality table was constructed by the Committee on Expected Experience of the Canadian Institute of Actuaries. The Canadian Institute of Actuaries has given the Society of Actuaries permission to reproduce this table as part of the Society's expansion of its experience studies. Discussions of this table as well as of any experience study are encouraged. The Canadian Institute and the Society intend to cooperate in producing experience studies to benefit actuaries in both Canada and the United States.

INTRODUCTION

The purpose of this report is to provide the details of the construction of a new mortality table based on experience over the period 1982 to 1988. This new table was produced by Harry H. Panjer and Giuseppe Russo at the University of Waterloo under the direction and guidance of the Committee on Expected Experience of the Canadian Institute of Actuaries. Separate tables are produced for males and females and for smokers and nonsmokers. The table uses a 15-year select period similar to the previous CIA table based on 1969-1975 experience.

Preliminary development was published in the paper "Parametric Graduation of Canadian Individual Insurance Mortality Experience—1982-1988" by Harry H. Panjer and Giuseppe Russo, which was distributed to members in November 1991 and will be published in the *Proceedings* of the Canadian Institute of Actuaries.

Modifications to the smoker/nonsmoker rate were made to reflect certain intercompany differences. A set of proposed mortality tables was included in a memorandum dated April 27, 1992, which was sent to members from the Committee on Expected Experience. The proposed tables were discussed at meetings of the CIA in March and June 1992.

THE DATA

The data were collected by the Committee on Expected Experience and reported annually in the Canadian Standard Ordinary Life Experience Reports published each year by the CIA. They are based on age last birthday.

The data cover policy years 1982 to 1988 and include almost 200,000 death claims. The data were available by numbers and by amount and were classified by sex, smoking status, and type of policy. Companies contributing to the 1987-1988 report and their respective exposures are given in Table 1. Tables 2 and 3 provide death claim and exposure information. Table 4 gives smoker-nonsmoker exposures by duration and shows that there is little data beyond the sixth duration. Only 18 percent of death claims indicated smoking status.

CONSTRUCTION AND FIT OF THE MODEL

The ultimate column was graduated first for males and females separately but with all other factors combined. Initial graduation was done using Whittaker-Henderson smoothing techniques. Final graduation at all but the youngest ages was done by fitting Makeham's Second Law using the method of weighted least squares. A cubic curve was fitted at the higher ages to fix a terminal age at 105. The fit of the graduation by quinquennial age groups is given in Table 5. A comparison of the graduated rates (age last birthday) to the CIA 1969-75 Table (age nearest birthday) is given in Table 6.

The ratio of first year to ultimate mortality was graduated using a linear-logistic curve declining from 1 at age 16 to about 26 percent for males and 21 percent for females at age 70. This curve measures the selection effect of the underwriting process in aggregate.

The rate of decay of the selection effect was modeled using a simple power function (approximately a square root function). It was found that the rate of decay of the percentage selection effect did not vary significantly by age or sex, although the amount of selection is greater at higher ages. Table 7 gives actual-to-expected ratios by duration for quinquennial age groups using triennial duration bands.

The aggregate tables in this report are those produced in the Panjer and Russo paper.

Tables 8 and 9 give ratios of smoker and nonsmoker deaths to expected deaths based on the aggregate table. In order to produce smoker and non-smoker tables for all durations (almost no data were available beyond duration seven), Panjer and Russo developed simple beta-type models for the

ratio of smoker to aggregate mortality. It was assumed that the ratio depends on attained age and not on duration. The model also assumed that smoker-to-aggregate and nonsmoker-to-aggregate ratios are 100 percent at the youngest and the highest ages. Due to limited female data, it was further assumed that the same model could be used for both sexes. Until more data are available, the assumptions are not easily testable. Details of the graduation process can be found in the Panjer and Russo paper.

Although the Panjer and Russo model fit the data well, changes to the smoker and nonsmoker tables were recommended by the Committee on Expected Experience. While some companies provided data that were split by smoking status, a significant proportion of the data was not split. The results in the Panjer and Russo paper were based on those companies that contributed data that were split in relation to all companies in aggregate. The companies that provided split data had overall mortality experience that was 87 percent of the aggregate for all companies. In order to produce a table more representative of overall industry experience, the parametric models used for the smoker-to-aggregate and nonsmoker-to-aggregate ratios were modified, so that actual-to-expected ratios are 87 percent based on the revised smoker and nonsmoker tables but retain the general shape as in the Panjer and Russo paper. This was done by modifying the parameters of the model. The revised parameters for the model described in Section 4 of the Panjer and Russo paper are $a = b = 3.5$ for smokers and $a = b = 3.0$ for nonsmokers. The parameter k is chosen so that the actual-to-expected ratio is 87 percent, resulting in $k = 6.22168E - 13$ for smokers and $k = 1.04510E - 11$ for nonsmokers. This results in the smoker-to-nonsmoker mortality ratios given in Table 10.
