# TRANSACTIONS OF SOCIETY OF ACTUARIES 1991-92 REPORTS 

# REPORT OF THE INDIVIDUAL LIFE INSURANCE EXPERIENCE COMMITTEE 

# MORTALITY UNDER STANDARD INDIVIDUALLY UNDERWRITTEN LIFE INSURANCE BETWEEN 1987 AND 1988 ANNIVERSARIES 

#### Abstract

This study is the latest in continuing annual reports on intercompany mortality experience under standard individually underwritten life insurance. The same 19 companies contributed their data to both the 1986-87 study and this study.

The mortality ratios in the report are based on the 1975-80 Basic Tables. The primary results for this study are as follows: - The overall mortality ratio in Table 1 for experience between 1987 and 1988 anniversaries, during policy years $1-15$, is 85.6 percent, down 0.7 percent from the prior year and continuing the ongoing trend. Unlike the prior study, medical ratios were more than 5 percent higher, but this was more than offset by corresponding improvements in both paramedical and nonmedical experience. - The mortality ratios in Table 7 for experience between 1983 and 1988 anniversaries, during policy years $1-15$, show a significantly greater improvement (compared to 1982-87 anniversaries) for females ( 3 percentage points, down to 91.9 percent) than for males ( 1 percentage point, down to 88.2 percent). The greatest improvement from the 1975-80 period is still at issue ages 30-39; however, the increasing adverse effects of AIDS claims in future studies may well reverse this trend for males at these ages. - For 1980-87 issues observed between 1983 and 1988 anniversaries, the mortality ratio in Table 18 for smokers is 148.7 percent and that for nonsmokers is 70.5 percent, virtually unchanged from the prior year. Subdivisions of these data into medical, paramedical and nonmedical and into male and female produced little difference in these overall ratios, except that the nonmedical ratios continue to be somewhat less than either the medical or paramedical ones. - For ultimate experience between 1987 and 1988 anniversaries, the overall mortality ratio in Table 22 is 86.3 percent, about a 5 percent decrease from 1986-87. The comparable mortality ratios using expected deaths based on the 1980 CSO tables and the 1979-81 U.S. Population Tables are 65.2 percent and 64.6 percent, respectively.

## INTRODUCTION

This report covers the intercompany (U.S.) mortality experience by amount of life insurance under standard individually underwritten issues between

1987 and 1988 anniversaries. The report also combines experience between 1983 and 1988 anniversaries in order to provide a larger volume of data, so that broader comparisons of results, particularly for males-females, for smokersnonsmokers, and for medical-paramedical-nonmedical issues, can be made.

INDEX OF PRIMARY TABLES

| Table | Exposure Period | Policy Years* | Medical, Paramedical, or Nonmedical | Male or Female | Smoker/ <br> Nonsmoker | Mortality Ratios by |

Appendix A - Names of the contributing companies and percentage of total 1987-88 exposures contributed by each company

[^0]The report is divided into four primary sections:
I. Select Experience (first 15 policy years) between 1987 and 1988 anniversaries for issues of 1973-1987 (Tables 1-6).
II. Select Experience (first 15 policy years) between 1983 and 1988 anniversaries for issues of 1973-1987 (Tables 7-15).
III. Smoker-Nonsmoker Experience (first eight policy years) between 1987 and 1988 anniversaries and between 1983 and 1988 anniversaries for issues of 1980-1987 (Tables 16-21).
IV. Ultimate Experience (policy years 16 and over) between 1987 and 1988 anniversaries and between 1983-1988 anniversaries (Tables 22-25), for issues of 1972 and prior.
Each section subdivides experience by insurance issued subject to a medical examination (medical), insurance issued subject to a paramedical examination (paramedical), and insurance issued without a paramedical or medical examination (nonmedical).
Most of the tables in this report show actual amounts of death claims (to the nearest $\$ 1,000$ ) and mortality ratios of actual-to-expected death claims based on the 1975-80 Male and Female Basic Tables. (Tables 1, 2 and 22 also show mortality ratios based on the 1965-70 Basic Tables.) In addition, Tables 1, 2, 7, 8, 16-21, and 22 show amounts exposed to risk (to the nearest $\$ 1,000,000$ ). All data in Sections I, II, and III were submitted separately for males and females.

The 1987-88 select and ultimate experience is derived from the contributions of the same 19 companies contributing to the 1986-87 study. The 1983-88 select and ultimate experience is derived from the contributions of 23 companies, 18 of which contributed data for the entire 1983-88 period. The 1987-88 smoker-nonsmoker experience is derived from the contributions of 15 companies, and the 1983-88 smoker-nonsmoker data are derived from the contributions of 13 companies. Appendix A gives the names and proportionate contributions of companies that contributed 1987-88 experience. Appendixes B, C, and D, which are not published here but can be obtained from the Society Research Department, contain detailed medical, paramedical and nonmedical experience, respectively, by ages at issue for each year of issue, for males and females separately.

The following summary tables show some interesting trends. Table A shows the change in proportions of policies issued by type of underwriting and reflects the substantially decreased use of medical examinations and increased use of nonmedicals. However, there is a reversal of this trend for

1987 issues, indicating that there may be more medicals and paramedicals used in connection with blood testing.

Table B shows mortality ratio by exposure years since the introduction of the 1965-70 Basic Tables. The decreases in the ratios are a continuation of the trend that has continued almost without exception since these annual studies were started.

TABLE A
Exposures for Policy year 1
As Percentage of Total Exposures

| Year of issue | Medical | Paramedical | Nonmedical |
| :---: | :---: | :---: | :---: |
| 1977 | $34.7 \%$ | 28.9\% | 36.4\% |
| 1978 | 35.1 | 28.5 | 36.4 |
| 1979 | 35.1 | 30.5 | 34.4 |
| 1980 | 38.2 | 32.5 | 29.3 |
| 1981 | 33.1 | 30.6 | 36.3 |
| 1982 | 29.2 | 25.1 | 45.7 |
| 1983 | 24.7 | 23.5 | 51.8 |
| 1984 | 22.5 | 25.3 | 52.2 |
| 1985 | 20.8 | 27.1 | 52.1 |
| 1986 | 15.7 | 27.3 | 57.0 |
| 1987 ..... | 17.1 | 30.9 | 52.0 |

TABLE B
aggregate Mortality Ratios Based on 1965-70 Select Basic Tables (Numbers in Parenthesis Are Mortality Ratios Based on the 1975-80 Basic Tables)

| Exposure Year | Policy Yeans 1-15 |  |  |  | Policy Years 16 and Dver |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Medical | Paramedical | Nonmedical | Combined |  |

| 1975-76 | 80.9 | 81.4 | 88.5 | 82.3 | 85.0 |
| 1976-77 | 75.5 | 78.0 | 87.9 | 77.9 | 82.0 |
| 1977-78 | 75.0 | 80.5 | 85.9 | 77.4 | 80.5 |
| 1978-79 | 68.7 | 74.5 | 84.9 | 72.1 | 77.0 |
| 1979-80 | 69.8 | 80.3 | 82.9 | 73.3 | 77.1 |
| 1980-81 | 69.5 | 70.1 | 79.8 | 71.0 | 75.2 |
| 1981-82 | 67.8 | 73.2 | 79.2 | 70.7 | 72.8 |
| 1982-83 | 68.0 | 69.9 | 74.2 | 69.6 | 73.2 |
| 1983-84 | 68.6(93.6) | 68.8(92.2) | 70.8(89.6) | 69.1(92.4) | $71.2(91.8)$ |
| 1984-85 | 66.2 90.5) | 69.9(94.3) | $72.4(92.5)$ | $68.5(91.9)$ | $71.0(91.1)$ |
| 1985-86 | 61.2(83.7) | 67.9(91.8) | 72.0(92.4) | 65.5(88.0) | $70.0(89.8)$ |
| 1986-87 | 57.8(79.1) | 68.0(91.9) | $71.5(92.0)$ | 64.2(86.3) | $71.0(90.8)$ |
| 1987-88 | $61.0(83.5)$ | 64.3(87.2) | 67.2(86.5) | 63.6(85.6) | 67.5(86.3) |

Table C shows the proportions of medical, paramedical and nonmedical exposures in policy year 1 and policy years $1-15$ by issuc age groups. This indicates that the use of nonmedicals predominates at issue ages under 30 and that medicals still account for about half of the exposures (which are based on amounts of insurance) at issue ages 50 and over.

TABLE C
Exposures as Percentage of Total Exposures for 1987-1988 Experience

| Ages at Lssue | Policy Year 1 |  |  | Policy Yeats 1-15 |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Medical | Paramedical | Nonmedical | Medical | Paramedical | Nonmedical |
| 0-9. | 2.7\% | 1.4\% | 95.9\% | 4.0\% | 1.7\% | 94.3\% |
| 10-19. | 2.4 | 3.7 | 93.9 | 4.5 | 3.5 | 92.0 |
| 20-29. | 2.9 | 8.9 | 88.2 | 6.7 | 11.2 | 82.1 |
| 30-39. | 12.1 | 32.5 | 55.4 | 18.3 | 31.8 | 49.9 |
| 40-49. | 27.7 | 51.2 | 21.1 | 34.5 | 45.7 | 19.8 |
| 50-59. | 45.2 | 45.5 | 9.3 | 49.8 | 41.6 | 8.6 |
| 60-69. | 57.9 | 34.2 | 7.9 | 59.6 | 34.9 | 5.5 |
| 70 and over | 65.5 | 27.1 | 7.3 | 70.4 | 24.2 | 5.4 |
| All Ages ..... | 17.1 | 30.9 | 52.0 | 21.4 | 28.1 | 50.5 |

It would be desirable for the comparisons of medical, paramedical and nonmedical experience to be based on strictly comparable policies, but such comparisons are not possible. Medically underwritten business generally includes larger amounts of insurance issued to persons at higher socioeconomic levels than nonmedical and paramedical business. However, medical business also includes policies issued to individuals within nonmedical or paramedical amount limits who were not acceptable on these bases because of medical histories. Similarly, paramedical policies include persons not acceptable on a nonmedical basis. In addition, there are considerable variations in amount limits and proportions of medical, nonmedical, and paramedical policies among contributing companies. In this comparison and throughout this report, the difference in the mix of companies from that in some previous studies may account for some of the differences in 1983-88 and 1987-88 mortality ratios.

Note also that some of the more recent nonmedical issues are likely based on applications with limited medical history questions (that is, simplified underwriting). In addition, nonmedical issues over age 50 often arise from business issued under pension trust and salary allotment plans. So-called
policyholder's nonmedical, issued on the basis of a previous medical examination within 6 or 12 months, is also included in nonmedical issues for some companies.

## I. 1987-88 EXPERIENCE (MALES AND FEMALES COMBINED)

The experience between 1987 and 1988 anniversaries during the first 15 policy years presented in Tables $1-6$ includes exposures of $\$ 687$ billion and actual deaths of $\$ 1,041$ million. The corresponding amounts in the $1986-$ 87 experience were $\$ 672$ billion and $\$ 980$ million, respectively. As previously mentioned, the same 19 companies contributed data for both 1986-87 and 1987-88.

The experience for the first 15 policy years compared by issue age group is shown in Table 1 and that by policy year is shown in Table 2. Separate data for medical, paramedical and nonmedical are shown by issue age group in Table 3 and by policy year in Table 4. Separate data for males and females (Tables 7-15) and for smokers and nonsmokers (Tables $16-21$ ) are shown later in this report.

| Total . | \$403,833 | 83.5\% | \$331,983 | 87.2\% | \$260,943 | 86.5\% |

The mortality ratio for medical, paramedical and nonmedical combined based on the 1975-80 Basic Tables is 85.6 percent. The mortality ratios for the subdivided experience are 83.5 percent for medical, 87.2 percent for paramedical and 86.5 percent for nonmedical. These aggregate ratios do not present an accurate comparison of these three sets of data because of the different age distributions.

## By Issue Age (Tables 1 and 3)

The pattern of mortality ratios by issue age shows relatively little improvement in mortality from the 1975-80 experience (that is, the experience underlying the 1975-80 Basic Tables) at issue ages under 25 and at issue ages 60 and over. However, there has been substantial improvement at issue ages 25-49.

The bulk of the exposures are nonmedical through issue age 29, and the nonmedical experience is generally more favorable than expected at these ages-presumably because much of the medical and paramedical issues were
within nonmedical amount limits but required examinations because of medical history. The data for issue ages $30-39$ include a substantial proportion of medical, paramedical and nonmedical, and not unexpectedly the mortality ratios are lowest for medical, almost as low for paramedical, but higher for nonmedical, particularly at issue ages 35-39.

At issue ages $40-59$, the bulk of the experience is medical and paramedical. The medical experience has relatively low mortality ratios, and the mortality ratios for paramedical increase with age. The amount of nonmedical data decreases with age and the mortality ratios increase with age.
At issue ages 60 and over, the medical experience continues to show relatively low mortality ratios, and the paramedical mortality experience produces high mortality ratios. The nonmedical data are very limited.

By Policy Year (Tables 2 and 4)
The mortality ratios by policy year for medical, paramedical and nonmedical separately are generally lowest in the first six policy years and highest in policy years $7-12$. This pattern may reflect lapsation and antiselection due to replacement of policies issued just prior to the introduction of interestsensitive products in the early 1980 s. Note that the paramedical experience is less mature (that is, there were relatively few paramedical issues before the mid-1970s), and therefore the amount of exposure is still relatively small at the longer durations.

Combined totals have been omitted from Tables 2 and 4, because they would be exactly the same as the corresponding male-female totals in Tables 1 and 3. This is because about 4 percent of the 1987-88 actual deaths ( $\$ 44+$ million) have not been identified as either medical, paramedical nor nonmedical issues. Separate combined ratios were not calculated for the 96 percent group of identified business.

## By Issue Age and Policy Year (Tables 5 and 6)

The 1987-88 experience is subdivided, separately for medical, paramedical and nonmedical, in Table 5 into six issue age groups, each further subdivided into four policy-year groups. These subdivisions provide an opportunity to examine the separate medical, paramedical and nonmedical data in more detail than that provided by issue age for all policy years combined (Table 3) and by policy year for all issue ages combined (Table 4).

Table 6 shows the ratios of mortality ratios: paramedical to medical, nonmedical to paramedical, and nonmedical to medical. Each of these would be expected to exceed 100 percent because in each case the ratio is that of the less exacting underwriting requirement to the more exacting. This is generally true except for the age groups for which the comparisons are distorted by small amounts of data (for example, medical and paramedical experience at ages under 30 , durations $1-5$ ).

## 11. 1983-88 SELECT EXPERIENCE (MALES AND FEMALES SEPARATELY)

The experience between 1983 and 1988 anniversaries during the first 15 policy years is presented in Tables 7-15 in the same format as that presented for the 1987-88 experience in Tables 1-6 except that data for males and femates are presented separately.

This experience includes exposures of $\$ 3.4$ trillion, and actual deaths of $\$ 5.1$ hillion. Corresponding $1982-87$ figures were $\$ 3.3$ trillion and $\$ 4.9$ billion, respectively.

The mortality ratio for 1983-88 medical, paramedical and nonmeaical experience combined (Table 7) is 88.8 percent (compared to 90.1 percent for the 1986-87 experience). The mortality ratio for males decreased from 89.3 percent to 88.2 percent and that for females decreased from 95.0 percent to 91.9 percent. These mortality ratios are based on expected deaths derived from the separate male and female 1975-80 Basic Tables.

## By Issue Age (Tables 7 and 9)

The mortality ratios by issue age (Tables 7 and 9) show a pattern for both males and females that is somewhat similar to the 1987-88 experience (Tables 1 and 3): relatively high ratios at issue ages 15-24 and relatively low ratios at ages $25-39$. However, the mortality ratios for females are much more than 100 percent at issue ages 55 and over, which may reflect a possibly higher degree of mortality-related antiselection at issue than may be the case for males. These patterns are consistent throughout the experience when subdivided into medical, paramedical and nonmedical.

## By Policy Year (Tables 8 and 10)

The increase in mortality ratios by policy year, followed by a decrease, again reflect the possible lapsation antiselection produced by the heavy replacement activities in recent years. However, this replacement has shown

signs of abating, due in large measure to the recent trends of declining interest rates. If these trends continue, they may start to affect the 1988-89 and later experience more favorably.

The same mortality pattern by policy year has become significantly more pronounced for females than for males, although the relatively favorable mortality in policy years $1-2$ is also apparent for females. The highest male paramedical mortality is for policy years $7-12$, and the highest male nonmedical mortality is for policy years 6 and over.

## Comparison of Medical, Paramedical and Nonmedical Experience

In the 1983-88 experience, the mortality ratios (using expected deaths based on the 1975-80 Basic Tables) of medical, paramedical and nonmedical separately, subdivided by males and females as compared to the combined mortality ratios in the 1987-88 experience, are summarized as follows:

|  | $1983-88$ |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
|  | Males | Females | Combined | $1987-88$ |
|  | Combined |  |  |  |
| Medical | $85.0 \%$ | $101.1 \%$ | $86.6 \%$ | $83.5 \%$ |
| Paramedical | 90.3 | 96.2 | 91.2 | 87.2 |
| Nonmedical | 93.1 | 82.9 | 90.5 | 86.5 |
| All | $88.2 \%$ | $91.9 \%$ | $88.8 \%$ | $85.6 \%$ |

These mortality ratios suggest the following observations:

1. The more favorable medical mortality ratio for the 1987-88 experience ( 83.5 percent) relative to the 1983-88 experience ( 86.6 percent) may be due to the increasingly greater proportion of medicals on large policies for which underwriting investigations are more extensive.
2. The more favorable 1983-88 nonmedical ratio for females ( 82.9 percent) relative to paramedical ( 96.2 percent) and medical ( 101.1 percent) suggests that examinations, because they largely identify cardiovascular risk profile characteristics (that is, build, blood pressure, pulse), may be of relatively less value in underwriting females at the older ages, where most of the relatively unfavorable paramedical and medical experience occurs.
3. As previously mentioned, the higher 1983-88 mortality ratio for females ( 91.9 percent) relative to males ( 88.2 percent) indicates less improvement

for females since the 1975-80 period on which the 1975-80 Basic Tables were based. However, this gap has narrowed somewhat, in contrast to 1982-87.

## By Issue Age and Policy Year (Tables 11-15)

Tables 11-14 subdivide the 1983-88 experience into the same six issue age groups and the same four policy-year groups as in Table 5. This provides an opportunity to examine the experience by issue age-policy year cells.

Table 15 shows the ratios of mortality ratios for the 1983-88 experience in the same way as Table 6 for the 1987-88 experience, except that Table 15 shows these ratios of mortality ratios separately for male and female. For males, as expected, the ratios of the less exacting underwriting requirement to the more exacting generally exceed 100 percent as in Table 6, except where the comparisons are distorted by small amounts of data. For females, the results are the opposite of what would be expected; the ratios of mortality ratios are generally less than 100 percent except for issue ages 50 and over (however, the amount of nonmedical data at issue ages 50 and over is quite small), and for issue ages under 20, where the amount of medical and paramedical data is also quite small.

## III. SMOKER-NONSMOKER EXPERIENCE

Tables 16-21 present smoker-nonsmoker experience for issues of 1980 through 1987, submitted by 16 of the 19 overall contributing companies. Tables 16 and 17 show the experience between 1987 and 1988 anniversaries separately for medical, paramedical and nonmedical, but for males and females combined, by issue age and policy year, respectively. Tables 18 and 19 show the experience between 1983 and 1988 anniversaries but are otherwise identical to Tables 16 and 17. Tables 20 and 21 show the 1983-88 experience subdivided by sex but not by type of underwriting.

For 1987-88 experience combined, the mortality ratio for nonsmokers is 71.1 percent, compared to 142.0 percent for smokers. For medical experience, the respective ratios are 72.8 percent and 146.5 percent; for paramedical, 68.6 percent and 146.0 percent; and for nonmedical, 72.4 percent and 133.3 percent.

| $\begin{aligned} & \text { Key: } \text { Med }=\text { medical } \\ & \text { Para }=\text { paramedical } \\ & \text { Non }=\text { nonmedical. } . \end{aligned}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

By issue age (Tables 16 and 18), the adverse effect of smoking is most apparent at ages $50-59$, where the mortality ratio for smokers is almost 2.5 times that for nonsmokers. By policy year (Tables 17 and 19), the medical mortality ratios for smokers are somewhat lower in the earlier durations ( $1-3$ ).

For the 1983-88 experience (Tables 18-21), the mortality ratios are as follows:

|  | Nonsmoker | Smoker | Ratio |
| :--- | :---: | :---: | :---: |
| Medical | $71.5 \%$ | $153.1 \%$ | 2.14 |
| Paramedical | 68.4 | 152.9 | 2.24 |
| Nonmedical | 71.6 | 140.3 | 1.96 |
|  |  |  |  |
| Male | 70.7 | 151.0 | 2.14 |
| Female | 69.4 | 137.2 | 1.98 |
| Total | $70.5 \%$ | $148.7 \%$ | 2.11 |

The ratio of smoker to nonsmoker mortality ratios is remarkably consistent. The lower ratio for nonmedical smokers reflects the younger age distribution, where the ratio of smoker-to-nonsmoker mortality is somewhat lower than at older ages. The lower ratios for female smokers may be due to lighter smoking on average among females than males.

The proportion of nonsmoker to total exposure is 82.9 percent for males and 82.5 percent for females; each is down slightly from the 1982-87 study ( 83.2 percent and 82.7 percent, respectively). This is a somewhat higher proportion than may have been expected, perhaps due to nonadmission of smoking habits by some smokers. Those who did not admit smoking may have been among the lighter smokers. The inclusion of some of the lighter smokers in the nonsmoker instead of the smoker group would have increased the mortality ratio for smokers more than for nonsmokers.

Note that the nonsmoker-smoker data are only on 1980-87 issues and are heavily concentrated in the earlier policy years. However, it does not appear likely that the overall ratio of smoker-to-nonsmoker mortality ratios will change greatly as the experience matures.

## IV. ULTIMATE EXPERIENCE (POLICY YEARS 16 AND OVER)

The experience between 1987 and 1988 anniversaries for policy years 16 and over is shown in Tables 22-25. The Table 22 mortality ratio based on the 1975-80 Ultimate Basic Tables has improved to 86.3 percent for all ages. This compares to 90.8 percent for the 1986-87 experience, 89.8 percent for the 1985-86 experience and 91.1 percent for the 1984-85 experience. (Note that the company mix changed somewhat each year, prior to 1986-87.) The ratios by attained age group are quite similar for ages $40-$ 84. However, for attained ages $25-39$, the ratios exceeded 100 percent, indicating an increase in mortality from the 1975-80 period from which mortality rates for expected deaths were obtained. This same mortality pattern appears in the 1985-86 and 1986-87 experience. Part of this extra mortality at younger ages could be attributed to AIDS deaths.

Table 22 also presents mortality ratios based on the 1965-70 Ultimate Basic Tables, the 1980 CSO Tables and the 1979-81 U.S. Population Life Tables (Whites and Non-Whites Combined). The mortality ratios based on the 1980 CSO and the 1979-81 U.S. Population Tables remain remarkably similar ( 65.2 percent and 64.6 percent, respectively) to the corresponding ratios for 1986-87 experience. By attained age, the CSO mortality ratios are lower than the population mortality ratios through attained age 44, higher for ages 45-74, and then lower again for ages 75 and over.

Tables 23, 24 and 25 show the experience between 1983 and 1988 anniversaries for policy years 16 and over subdivided in three ways. In Table 23 , the mortality ratio for fully paid-up policies (reduced paid-up policies are not included) is 92.7 percent compared to 89.4 percent for premiumpaying policies. Corresponding ratios for 1982-87 experience were 93.7 percent and 91.1 percent, respectively. These lower mortality ratios for pre-mium-paying policies have been a characteristic of the experience for many years.

The mortality ratios for medical ( 86.9 percent) and nonmedical (101 percent) issues are presented in Table 24. This large difference in mortality ratios exists for virtually all attained-age groups. This result may be due more to lapsation antiselection among nonmedical policies than to the more rigorous initial selection applied to medical policies. As a result of higher lapse rates (generally by the better risks), the nonmedical exposure may contain an increasingly higher proportion of poorer risks than the medical experience.

Mortality ratios for males and females are presented in Table 25 . However, the female mortality ratios used to calculate the female-to-male ratio of mortality ratios in the last column are based on the 1975-80 Ultimate Male Basic Table, so that male and female mortality ratios can be compared on the same basis. The female ultimate mortality ratio is 90.4 percent (down only from 90.5 percent for the 1986-87 experience), while the male ultimate mortality improved to 89.8 percent, down from 91.2 percent in the 198687 study. As a result, the ratio of female-to-male mortality increased by 1 percent, to 62 percent. This ratio varies from less than 50 percent at attained ages $15-34$, due to the relatively low accidental death rate of females at these young ages (where accidents are a primary cause of death), up to close to 70 percent at attained ages 40-54, down to about 60 percent at attained ages 55-84 where females are less subject to coronary artery disease.
