TRANSACTIONS OF SOCIETY OF ACTUARIES 1954 VOL. 6 NO. 16

## PRUDENTIAL MORTALITY EXPERIENCE BY SEX

E. A. RODE

SEE PAGE 48 OF THIS VOLUME
J. R. MCDONNELL:

In the opening paragraph of his informative paper, Mr. Rode expressed the thought that members of the Society might be interested in the results of a study made by the Prudential for the purpose of obtaining their mortality experience by sex. The results of that study were of considerable interest to us at the New York Life.

TABLE 1

| Policy Years | Issues Ages 10-64 |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Medical |  | Nonmedical |  | Medical and Nonmedical |  |
|  | $\begin{gathered} \text { Actual } \\ \text { Claims } \\ \text { (in } 1,000 \text { 's) } \end{gathered}$ | Ratio of Actual to Expected | $\begin{gathered} \text { Actual } \\ \text { Claims } \\ \text { (in } 1,000 \text { 's) } \end{gathered}$ | Ratio of Actual to Expected | $\begin{gathered} \text { Actual } \\ \text { Claims } \\ \text { (in } 1,000 \text { 's) } \end{gathered}$ | Ratio of <br> Actual to <br> Expected |
|  | Male Lives |  |  |  |  |  |
| 1-2 | \$ 1,515 | 105\% | \$ 352 | 107\% | \$ 1,867 | 105\% |
| 3-5. | 2,477 | 101 | 396 | 118 | 2,873 | 103 |
| 6-10. | 6,153 | 107 | 511 | 114 | 6,664 | 107 |
| 1-10 | \$10,145 | 105\% | \$1,259 | 113\% | \$11,404 | 106\% |
|  | Female Lives |  |  |  |  |  |
| $\begin{aligned} & 1-2 \\ & 3-5 \\ & 6-10 . \end{aligned}$ | \$ 109 | 62\% | $\$$6750152 | $\begin{aligned} & 74 \% \\ & 45 \\ & 71 \end{aligned}$ | \$ $\begin{array}{r}176 \\ 354 \\ \\ \\ \hline 71\end{array}$ | $\begin{aligned} & 66 \% \\ & 81 \\ & 56 \end{aligned}$ |
|  | 304 | 93 |  |  |  |  |
|  | 419 | 51 |  |  |  |  |
| 1-10 | \$ 832 | $63 \%$ | \$ 269 | 65\% | \$ 1,101 | 64\% |

Earlier this year, we made an analysis of our current mortality experience by sex. The scope of our study, however, was not as extensive as that described in Mr. Rode's paper. Briefly, our results were based on an analysis of the experience between 1952 and 1953 policy anmiversaries by
amount of insurance. The study covered issue ages 10 to 64 , inclusive, under our standard issues of 1943 through 1952. War deaths were excluded.

In our study, expected deaths were based on crude mortality rates developed, for medical and nonmedical business separately, from the corresponding actual combined male and female experience. Ratios of actual to expected claims for male and female lives separately were then ob-

| 10-64 | \$ 832 | 63\% | \$ 269 | 65\% | \$ 1,101 | 64\% |

* Age 40 maximum issue age under nonmedical program.
tained for (1) medically examined business; (2) nonmedical business; and (3) medical and nonmedical business combined. Our results are summarized in the two tables above.

As shown in the tables, the over-all ratios of actual to expected claims for policy years 1 to 10 for medical and nonmedical business combined were $106 \%$ for males and $64 \%$ for females. Since the results of the Prudential's study were not given in exactly the same form as that which we had used in our study, it was not convenient to make a direct comparison of
results. However, it appears that if ratios of actual to expected claims for all amounts combined were to be determined from the Prudential data for policy years 1 to 10 only and for issue ages 10 to 64 , inclusive, the overall results would be fairly close to those which we obtained from our experience.

The results of these two studies confirm the well recognized fact that mortality on female lives has been favorable in relation to that experienced on male lives. However, mortality is only one of several factors which must be taken into account in computing premium rates. Thus, favorable mortality on females may be offset by higher unit expenses resulting from smaller average size policies. This is particularly true at the younger ages where most of the business on women is written and where mortality rates are normally low so that mortality savings are small on a dollar and cents basis. The effect of the various factors involved was fully discussed this year in the "Informal Discussion" at the 1954 Eastern and Western Spring meetings.

With respect to average size policy on female lives, an analysis of our paid standard issues over a two months period in 1954 showed a figure of about $\$ 2,500$ on females as compared with an average size policy of about $\$ 6,200$ on male lives.

With respect to the relatively heavy concentration of new issues on female lives at the younger ages where the effect of favorable mortality is less important financially, the above mentioned analysis of 1954 paid issues showed that, for new issues on female lives, about $73 \%$ by number of policies and about $56 \%$ by amount were written at issue ages below 30 . The corresponding figures for male lives were $56 \%$ and $41 \%$, respectively.

Mr. Rode also mentioned in his paper that the Prudential had underwritten married women nonmedically since 1943 with an amount limit one-half of that for males and single females. We have been more liberal in that regard and, in our nonmedical programs, have always applied the same amount limits to male and female lives, regardless of marital status.

WALTER G. BOWERMAN:
In this report Mr. Rode has made a study of standard Ordinary issues of 1919 to 1951, exposed between 1948 and 1952. The death rate of females was $65 \%$ of that of males (much lower than in earlier reports!). At ages 10-24 the ratio of female to male mortality was lower than that of the general population. At older ages ( $25-70$ ) it was higher. The only marked excess was at ages $30-39$. Probably these Ordinary lives in the Prudential were a bit more on the industrial side than is true of the entire U.S. population. Seventy percent of the business was written by agents
who sell both Ordinary and Debit lines. Thus the hazards of childbirth would stand forth as a differentiating factor.

About $15 \%$ of the business was on female lives. Of the total amount in force in 1950 at issue ages $0-29$, as much as $71 \%$ was written without medical examination (a high proportion!).

For all the present data the lowest nonselect mortality at any age was .35 per 1,000. This was at attained age 9 in each of the policy years 6 to 10 (a very low "ultimate" death rate). However, it was higher than the . 25 per 1,000 at the same age for girls in a recent tabulation for the population of New Zealand!
(AUTHOR'S REVIEW OF DISCUSSION)

> E. A. RODE:

I want to thank Mr. McDonnell and Mr. Bowerman for their discussions. The New York Life experience presented by Mr. McDonnell is a welcome addition to the paper, especially since it gives results for medical and nonmedical business separately.

We got the following ratios by summarizing our select data by amounts for issue ages $10-64$ in the same age and duration classes as Mr . McDonnell's:

|  | Ratto of Acteal to Expected |  |
| :---: | :---: | :---: |
|  | Male | Female |
| Policy Years |  |  |
| 1-2. | 102\% | 72\% |
| 2-5. | 100 | 70 |
| 6-10. | 103 | 57 |
| 1-10 | 102 | 63 |
| Ages at Issue |  |  |
| 10-29... | 104\% | 64\% |
| 30-39 | 102 | 91 |
| 40-49. | 101 | 52 |
| 50-64 | 100 | 50 |
| 10-64 | 102 | 63 |

Whereas the over-all results of the two experiences are similar, our female mortality is higher at ages $30-39$, and lower above age 40 than the New York Life's.
